MODULES:

- It is ES6 feature.
- Modules are used to break our code into separate files. This helps to maintain a code base.
- Modules are exported from external file.
- Exported modules are imported with import statements.

index.html:

```
<!DOCTYPE html>
<html lang="en">
<head>

<meta charset="UTF-8">
<meta name="viewport" content="width=device-width, initial-scale=1.0">
<title>Document</title>
</head>
<body>

<script src="./index.mjs" type="module"></script>
<!-- browser wont understand this module so we need specify type="module" -->
</body>
</html>
```

Note: Browser will not understand modules. So in modules it is mandatory to mention type = "module" inside the script tag of index.html as shown above

Exporting and importing a module:

Exporting a module:

- JS allows us to export a variables, functions, objects by using the export keyword.
- There are 2 types of exports
 - a) Named Exports:
 - ✓ In named exports we can export multiple module.

- ✓ We are exporting modules (variable, functions, objects) with their name.
- ✓ Named exports are imported using { } ({} indicates destructuring)
- ✓ <u>Note:</u> In named exports while importing the modules we have to import it by their names and {} mandatory.
- b) Default Exports:
 - ✓ Only one default export in a file.
 - ✓ While importing default exported module we can give any name.

Importing a module:

- To import a module, we need to use the import keyword.
- To import the modules we need to specify the path.
- When you import the **named** export, you must have to use the same name as the corresponding object inside { }.
- When you import the **default** export, we can give any name.

Named importing and exporting

Ex: In-line individually exporting

```
app.js
example for variables
export let course = "Java Fullstack"
export let technology = "React JS"

index.mjs
import { course,technology} from "./app.js"
console.log(course);
console.log(technology);
```

Example for function

app.js

```
export let message = () => {
    console.log("Please concentrate students");
}

export let add = (a, b) => a + b;

index.mjs

import { message,add } from './app.js'

message()
console.log(add(2,3));
```

Ex: Exporting all at once app.js

example for variables

```
let course = "Java Fullstack"
let technology = "React JS"

export {course,technology}

index.mjs

import { course,technology} from "./app.js"

console.log(course);

console.log(technology);
```

Example for function.

```
app.js

let message = () => {
    console.log("Please concentrate students");
}

let add = (a, b) => a + b;

export {message,add}

index.js

import { message,add } from './app.js'

message()

console.log(add(2,3));
```

Default importing and exporting

Examples for variables

```
app.js

let name = "Ram"
export default name;

index.js

//we can give any variable name while importing
//Here in a , name variable is stored
//So if we console.log(a) we get "Ram"
import a from "./app.js"
console.log(a);
```

Example for function

```
app.js

let fun = () => {
    console.log("hiiiii");
}
export default fun;
```

index.mjs

```
//we can give any variable name while importing
//Here in b , fun function is stored
//So if call b(), fun function is called
//we will get output as hiiiii
import b from "./app.js"
b()
```

Note: In index.js file while importing modules from any file it is mandatory to mention .js extension that is "./app.js"
